SECTION 1

Introduction

This memorandum summarizes geotechnical conditions along the Dallas Road alignment of the Clover Forcemain, reviews geotechnical conditions affecting design of the forcemain, and outlines the next steps for geotechnical work required to complete detailed design. This memorandum is based on Kerr Wood Leidal Consulting Engineers' (KWL) review of the indicative design prepared by Stantec Consulting Ltd (Stantec), results of geotechnical investigations and reference reports, information presented at meetings with Capital Regional District (CRD) and Stantec staff, and a site reconnaissance.

The KWL team concluded that with refinement of the indicative design, the Dallas road alignment is suitable for construction of the Clover Forcemain from a geotechnical perspective and that the forcemain can be constructed and operated without an adverse effect on the Dallas Road Bluffs and James Bay Seawall.

1.1 Project Background

The Clover Forcemain is an essential part of the CRD Wastewater Treatment Project, which will convey and treat wastewater from the CRD Core Area. On September 14, 2016, the CRD Board approved the Wastewater Treatment Project, including the proposed Clover Forcemain.

The Clover Forcemain will convey wastewater from the Clover Point Pump Station to Ogden Point. The alignment of the proposed Clover Forcemain is shown in Figure 1-1. At Ogden Point the forcemain will connect to the Harbour Crossing project, which consists of a pipe crossing under the entrance to the Victoria Harbour and conveying wastewater from the Clover Forcemain to the McLoughlin Point Wastewater Treatment Plant. The Clover forcemain will have a total length of approximately 3.4 km from the Clover Point Pump Station to Ogden Point.

CRD engaged Stantec to prepare an indicative design of the Clover Forcemain. In developing the indicative design, Stantec evaluated route options, selected a preferred route, developed the basis of design, prepared detailed alignment drawings, and estimated construction costs. CRD then engaged KWL to review the indicative design, prepare detailed design documents and be responsible for fulfilling Engineer of Record duties as defined by the Association of Professional Engineers and Geoscientist of British Columbia (APEGBC).

Figure 1-1 shows the alignment of the Clover Forcemain as developed by the indicative design.

CRD obtained a Licence of Occupation from the City of Victoria for the Clover Forcemain on February 22, 2017. CRD was granted a non-exclusive licence of occupation to install, entrench, construct, operate, maintain, and repair the forcemain. Construction of the Clover Forcemain will include mitigation of environmental, geotechnical, and archaeological impacts, as well as construction of a cycle track along Dallas Road from Clover Point to Dock Street.

This memorandum summarizes the geotechnical aspects of the Dallas Road alignment affecting design.

Figure 1-1. Clover Forcemain Location Map and Site Considerations

1.2 Project Objectives

CRD developed the following objectives for the Clover Forcemain Project:

- Provide for safe construction and operation.
- Completion by March 2020 to allow for commissioning of the wastewater system to comply with federal law for secondary treatment by December 31, 2020.
- Convey 162 megalitres per day of wastewater from the proposed Clover Point Pump Station to the Harbour Crossing project at Ogden Point.
- Remain operational during and following a seismic event.
- Preserve the integrity of the sensitive ecosystem of the Dallas Road Bluffs.
- Mitigate construction and operational risks associated with environmentally sensitive areas, including those in close proximity to the Dallas Road Bluffs.
- Assess and mitigate risks associated with registered archaeological sites in proximity to forcemain.
- Address geotechnical challenges, including those associated with construction and operation of a
 forcemain in close proximity to the Dallas Road Bluffs and the Dallas Road Seawall. This includes
 possible impacts of the forcemain on the Bluffs and Seawall and possible impacts of the Bluffs and
 Seawall on the forcemain.
- Minimize construction and operational impacts to high-use areas by community users and tourists.
- Minimize total cost to regional taxpayers (including capital and life cycle costs).

1.3 Design Criteria

To implement the objectives established by CRD for the Clover Forcemain, Stantec developed the following design criteria:

- Seismic design loading is based on recurrence interval of 1 in 975 years and includes tsunami impacts and the effects of sea level rise
- Pipe material will be high density polyethylene (HDPE) with a dimension ratio of DR21
- Design for velocities no lower than 0.9 metres per second and not exceeding 1.5 metres per second.
- Where open cut construction is used, provide a minimum depth of cover of 1.0 metre

1.4 KWL Team Qualifications

Stantec prepared an indicative design for the Clover Forcemain. KWL has been engaged to complete the design of the forcemain. The scope of KWL's work includes a review of geotechnical factors affecting Stantec's indicative design.

KWL assembled an interdisciplinary team with expertise in the fields of conveyance system design, geotechnical engineering, terrain analysis, marine construction, environmental analysis, and civil engineering. On September 8, 2017, the KWL team, Stantec, and CRD Program Management Office staff held a workshop to review the entire Clover Forcemain along Dallas Road from Clover Point to Ogden Point, with a focus on assessing and refining design of the forcemain. Extensive consideration was given to the geotechnical aspects of the design, as well as schedule, cost, archeological impacts, environmental impacts, and community impacts.

The qualifications of the team are shown in Table 1-1.

Table 1-1
KWL Team Qualifications

Company	Relevant Qualifications	Member	Role/Specialty	Years of Experience	Degrees
Kerr Wood Leidal	Extensive familiarity with the Dallas Road Bluffs,	Colin Kristiansen, P. Eng.	Project Manager	26	BASc, MBA
	including preparation of a conservation plan for the bluffs that considered vegetation impacts, geotechnical assessments, climate change impacts and an archaeological overview.	Dave Murray, P.Eng.	Civil Engineering Specialist	28	BSCE, Dip. Civil
CH2M Hill	Expertise in design of large diameter forcemains with	Joe Broberg, P.Eng. ⁽¹⁾	Large Diameter Forcemain Specialist	43	BSCE, MSCE, MBA
	specialists in seismic design and resiliency of large diameter forcemains	Donald Anderson, P.E.	Seismic Specialist	43	BSCE, MSCE, PhD, D.GE
	including ground improvements and trenchless technology.	Andrew Finney, P.Eng	Trenchless Technology	24	BSCE, MSCE
Thurber Engineering	Geotechnical specialists having extensive local experience that includes the Dallas Road Bluffs, with specialists in the field of slope stability and terrain hazard assessments.	Stephen Bean, P.Eng.	Geotechnical Specialist	31	BASc, M.Eng
Plan Dynamics Ltd.	Environmental specialists, having extensive local experience in terrestrial and aquatic habitat, species at risk, ecology, etc.	David Harper CPESC, MCIP, RPP	Environmental Specialist	43	B.A., M.A., Ph.D.
Millennia Research	Archaeological expertise with extensive experience in local archaeological assessments and impact studies.	D'Ann Owens, ⁽²⁾ RPCA	Archaeology Specialist	23	BA (Hons)

⁽¹⁾ Joe Broberg is the Technical Review Leader.

1.5 Previous Work

The KWL team reviewed extensive information regarding CRD's Project, indicative design of the Clover Forcemain, and geotechnical factors affecting design of the pipeline, as well as archaeological and environmental considerations. This information was reviewed during KWL's assessment and included

Millennia Research was retained directly by the Project Team to provide archaeological services for the Project. D'Ann Owens participated in the review of archaeological issues for the Clover Forcemain.

results of previous geotechnical investigations and reference documents, meetings, and a site reconnaissance. The project team provided a summary of public feedback and comments that were considered in the preparation of this memorandum.

KWL also has extensive experience with the Dallas Road Bluffs, including preparation of a conservation plan. This plan included an overview of coastal geomorphology and past geotechnical studies, a geotechnical inspection and inventory, a detailed vegetation inventory and proposed restoration prescriptions, and a review of plant species at risk. This information was used to develop an overall bluff restoration plan which included identification of priority areas, removal of invasive species, cultivation of rare species and restoration of the bluffs with native species in a phased approach. Drainage issues and future coastal erosion protection projects were also identified including the use of beach nourishment along the Dallas Bluffs. Subsequent to the study, KWL has provided engineering design and construction services for some minor erosion sites that required immediate action, some using bioengineering solutions.

Table 1-2 provides a list of reference documents that the KWL team consulted during review of the indicative design.

Physical and Geological Setting

This section summarizes the physical and geological setting of the Clover Forcemain, shoreline conditions, previous geotechnical investigations and a summary of the findings of the geotechnical assessment conducted by the KWL team.

2.1 Physical Setting

The ground surface along the length of the Clover Forcemain alignment ranges from flat to moderately sloping. The west third of the alignment, between St. Lawrence Street and Boyd Street is gently sloping. The middle third of the alignment is moderately sloping. The eastern third of the alignment is gently to moderately sloping, with a minor undulation near Linden Avenue but a general decrease in ground surface elevation from Beacon Hill Park to the Clover Point Pump Station. The ground surface perpendicular to the forcemain is generally flat to gently sloping, and is at least 15 m from the edge of slopes leading down to the beach, except near the James Bay Seawall, near Paddon Avenue, and near Douglas Street. The James Bay seawall spans approximately 500 m from Dock Street to Lewis Street and has a height of approximately 6 m measured from the ground surface behind the wall to the ground surface in front of the wall. Existing underground utilities run underneath Dallas Road along much of the alignment. There is a higher concentration of utilities between Ogden Point and Beacon Hill Park near Douglas Street. Overhead power and communication lines also run along the south edge of Dallas Road near Ogden Point, between St. Lawrence Street and Montreal Street.

2.2 Geological Setting

The forcemain alignment is located at the southern tip of Vancouver Island along the Dallas Road shoreline. The geology of the area consist of bedrock overlain by glacial deposits and recent fill. The bedrock in this area consists of highly irregular, glacially scoured granitic and metamorphosed granitic rock. The rock is typically hard, with unconfined compressive strengths in the 50 MPa to 250 MPa range and is crossed with numerous joints and shears. The surface of the bedrock is very irregular and often steeply sloping with granular tills filling in the bedrock valleys. As the ice from the last glaciation retreated, it deposited a layer of dense gravelly, silty sand beneath the ice (lodgement till) and submerged layers of less dense gravelly, silty sand (ablation and flow till). These tills are exposed along much of the current Dallas Road bluffs, particularly between Holland Point and Clover Point. As the ice retreated, large quantities of rock flour were deposited that formed a thick layer of Victoria marine clay. This clay is typically near normally consolidated (grey clay) with a desiccated crust (brown clay) up to about 5 m thick that has resulted from glacial rebound. In some areas, anthropogenic fills and beach lag deposits overly the marine clay.

2.3 Shoreline along Dallas Road

The shoreline along Dallas Road consists of bedrock points and steep south facing bluffs of glacial deposits up to about 20 m high. The bluffs are subject to a number of processes including toe erosion from storm waves, rotational landslides, colluvial creep and sloughing, wind, groundwater discharge, spalling by frost action and human activity that lead to slope regression. Over the last 100 years or so the City of Victoria has attempted to reduce the rate of natural regression through the construction of seawalls, revetments, stairways, retaining walls, drainage improvements, bioremediation (vegetation), off shore reefs and other methods. These bluffs are a prominent feature of the Victoria landscape, requiring that the forcemain be designed and constructed such that the rate of natural regression is unaffected by the forcemain project, and at locations where the existing risk of bluff instability is too high, stabilized to protect the forcemain from the natural regression of the bluff.

2.4 Subsurface Investigation

In June and July 2017, Stantec drilled 24 test holes and installed three slope inclinometers and a nested standpipe piezometer to investigate the soil conditions along the proposed Dallas Road alignment. The geotechnical exploration program was designed to identify:

- Areas which may be underlain by shallow bedrock.
- Areas potentially underlain by significant amounts of fill placed for road widening or pedestrian walkways.
- Areas where the stability of existing slopes could be impacted.
- Required instrumentation for geotechnical monitoring during and after construction of the forcemain.

The geotechnical exploration work included drilling using percussive air rotary and solid stem auger techniques; sampling by means of split spoon and grab sampling; in-situ testing by means of standard penetration testing (SPT's) and dynamic cone penetration tests and laboratory testing, including moisture content, Atterberg Limits, particle size, fines content, pH, conductivity, and sulphate content testing. A copy of the geotechnical factual report is appended.

Stantec also conducted preliminary slope stability analyses and estimated seismic ground displacements to assist in the indicative design.

2.5 Analysis of Geological Data

After reviewing available geotechnical data, the KWL team confirmed that the forcemain can be designed, constructed and operated within the Dallas Road corridor without impacting the bluffs and without the bluffs impacting the forcemain. The assessment identified the following geotechnical considerations affecting design of the Clover Forcemain.

2.5.1 James Bay Seawall Stability

The James Bay Seawall was constructed in 1912. The seawall is about 6 m in height and is believed to consist of a cast-in-place concrete gravity wall structure that has undergone numerous upgrades and modifications over the last 100 years or so. The geological conditions along this section of the alignment consist of fill materials and wall backfill overlying thick marine clay deposits. The wall backfill appears to be mixed clay and granular backfill in a relatively loose state. The marine clay deposit is known to become firm to soft beneath the wall. The geotechnical risk to the forcemain in this area would be a collapse of the seawall due to a seismic event, tsunami, or excessive wave erosion (undermining).

In the opinion of the KWL team, there is a strong likelihood that the seawall will undergo significant deformation during the design seismic event. However, there is sufficient space within the Dallas Road corridor to shift the forcemain alignment far enough away from the seawall to protect the forcemain from the seawall.

2.5.2 Bluff Stability

Along the bluffs to the east of the James Bay Seawall, there are three locations (described below) that appear to create a potential risk to the forcemain from bluff instability due to the proximity of the forcemain to slopes with existing stability problems. Bluff instability from natural processes, such as seismic loading and erosion, could endanger the forcemain at these locations even though the forcemain will be designed and constructed to not affect bluff stability. At other bluff locations, the setback of the forcemain to the bluff is believed to be such that the risk of bluff instability to the forcemain is minimal, and this will be confirmed through the development of the detailed design.

At other bluff locations, the setback of the forcemain to the bluff is believed to be such that the risk of bluff instability to the forcemain is acceptable, and this will be confirmed through the development of the detailed design.

- Paddon Avenue There is a long history of slope movement at the foot of Paddon Avenue. Since the 1950s, numerous attempts to improve the stability of this section of the bluffs have been carried out by the City. These include dumping fill over the edge of the slope, beach nourishment and various retaining walls at the base, mid-slope and crest of the slope. It appears that toe erosion has been reduced at this location; however, extensive cracking currently observed around the crest of the slope indicates that slope movement is still occurring.
- **Douglas Street** At the foot of Douglas Street there is a small pocket beach named "Fonyo Beach" at the base of an oversteepened bluff. This beach has no significant toe protection and active erosion on the slope can be observed. The indicative design recommended that the forcemain be located at least 9 m away from the crest of the slope to reduce the risk of ground movements during a seismic event. Further setback beyond 9 m is recommended to protect against natural toe erosion and slope regression during the service life of the forcemain.
- **Cook Street** At Cook Street, the bluff is near the proposed forcemain alignment and there is a concern about groundwater flowing along the pipe trench and adversely affecting the bluffs.

2.5.3 Presence of Granitic Rock at Ogden Point

An open trench in the Ogden Point area will encounter bedrock in some areas. The rock consists of hard, metamorphosed granitic rock which will require blasting for economic removal. The proximity to structures will require controlled blasting techniques and vibration monitoring. The proximity to structures will require mechanical removal or controlled blasting techniques and vibration monitoring. Additional investigation may be required in this area to better define the location and consistency of bedrock and the potential for poor quality fill..

2.5.4 Possibility of Liquefaction Near Ogden Point

The area of Ogden Point is known to contain large quantities of man-made fill materials used to construct the current cruise ship terminal area. These fills may extend to Dallas Road. The soils west of Dallas Road could be liquefiable and may require widespread ground improvement to protect the pipeline from flotation, settlement and lateral loading from liquefaction-induced lateral spreading. Along the current alignment of Dallas Road, only localized areas of ground improvement for liquefaction are envisaged.

2.5.5 Trench Water Management

The KWL team identified a need for design features that address management of water in the trench, including preventing uncontrolled flow of water in forcemain backfill. This will be addressed in detailed design.

SECTION 3

Conclusions and Recommendations

The KWL Team developed the following geotechnical conclusions and recommendations:

- 1. **No impact on Dallas Road Bluffs** The Clover Forcemain can be designed, constructed, and operated in the Dallas Road alignment without: affecting the Dallas Road Bluffs, and without natural forces affecting the forcemain.
- 2. **KWL** will design solutions addressing concerns with the Dallas Road Bluffs KWL will develop design solutions for locations where the forcemain is near the bluffs to achieve the goals of protecting the bluffs and the forcemain. These design solutions will address refinement of the forcemain alignment within the right of way of Dallas Road and inclusion of features to manage the flow of water in the forcemain trench.
- 3. **James Bay Seawall** Refinement in the alignment of the forcemain will avoid destabilizating the James Bay Seawall, and protect the forcemain from failure of the seawall.
- 4. **Investigations and analyses during detailed design** Further investigations and analyses will be completed during detailed design to develop design details and refine the indicative design.

Next Steps

Additional geotechnical information and analyses will be completed during detailed design to develop design details protecting the forcemain, bluffs, and seawall at the following four locations:

- James Bay Seawall
- Paddon Avenueand specifications, and will be responsible for fulfilling
- Douglas Street
- Cook Street

Details of the geotechnical investigations are provided below. Once the investigations have been completed, KWL will prepare detailed design drawings and will be responsible for fulfilling the duties of Engineer of Record as defined by APEGBC.

The additional geotechnical information and analyses will be used to develop design details refining the indicative design to assure protection of the bluffs and seawall from construction and operation of the forcemain and to protect the forcemain from natural forces affecting the bluffs. As part of completing the detailed design, KWL will prepare a plan to mitigate impacts of construction on the bluffs, including post-construction monitoring for 12 months following completion of construction. KWL will monitor the construction contractor's compliance to that plan.

4.1 Additional Test Holes and Laboratory Tests

It is proposed to drill an additional test hole at each of the 4 sites using a track-mounted sonic drill rig. The sonic rig will be used to advance the test holes from the roadway to approximately 15 m to 20 m depth unless refusal is encountered at a shallower depth. Periodic Standard Penetration Tests (SPT) will be completed at selected depths to allow an estimate of the relative density of the soil.

Soil and groundwater conditions will be logged in the field by experienced geotechnical personnel, the sonic core will be photographed, and disturbed samples will be collected from the core and returned to a soils laboratory in Victoria. All soil samples will be subjected to routine moisture content and visual classification testing in the laboratory. Fines content (% passing 75 μ m sieve) and Atterberg limit testing will be carried out on select representative samples.

4.2 Downhole Seismic Testing

Upon completion of drilling, downhole seismic testing (DST) will be conducted to provide an in-situ shear wave velocity (V_s) profile at each test hole location. A 63.5 mm (2.5" ID) PVC pipe will be grouted into each test hole location to facilitate insertion of the downhole seismic geophone. The geophone will take shear wave velocity measurements at 1 m intervals that will be used to estimate the small-strain shear modulus. The small-strain shear modulus is required to carry out a seismic site-specific response analysis (SSRA), which is used in the assessment of liquefaction potential and for numerical seismic deformation modelling.

4.3 Site-Specific Seismic Response Analysis, Limit Equilibrium Analysis, and Numerical Deformation Analysis

After drilling and laboratory testing is complete seismic assessments will be completed at each of the four areas of concern using both limit equilibrium and numerical analyses. The seismic assessment will be based on the 1 in 975 year return period earthquakes (design criteria) using seismic hazard values

available from Natural Resources Canada. Seismic ground deformations will direct design of the forcemain.

Both the limit equilibrium and numerical analyses will require site-specific seismic response analyses (SSRAs) to be carried out. SSRAs will be completed based on the shear wave velocities obtained from the DSTs. The SSRAs will result in a more precise estimation of ground motion amplifications than using the factors provided in the B.C. Building Code (BCBC).

The limit equilibrium analysis will be used to quantify horizontal seismic displacements of the force main at its preferred alignment. This analysis will use the software program Slope/W to identify the critical slip surface that intersects the forcemain and the corresponding seismic slope yield acceleration at each area of concern. The slope stability models will follow the ground surfaces and subsurface soil profiles. The horizontal displacements will be estimated based on an empirical correlation to Newmark's method using the peak ground accelerations (pgas) determined from the SSRAs, slope yield accelerations and slope geometries.

The results from the limit equilibrium analysis will be used to prioritize the areas for numerical deformation analyses. A numerical deformation analyses will be performed. The numerical deformation analysis will be carried out using the earthquake time-histories obtained from the SSRAs. Deformation contours will be generated at each of the four sites. This will assist in design of the forcemain at each of the four areas of concern.

1 INTRODUCTION

1.1 BACKGROUND

Stantec Consulting Ltd. (Stantec) presents this Geotechnical Factual Data report in support of Capital Regional District's (CRD) Clover Point Forcemain project. The preliminary Clover Point Forcemain alignment is located along Dallas Road in Victoria, BC and will run approximately 3.3 km from the existing Clover Point pump station to Ogden Point. However, the extent of Stantec's scope is for about 3.2 km of the alignment. A site plan showing the preliminary alignment is presented on Drawing 1 in Appendix B. The design and construction of the Clover Point Pump Station, as well as an approximate 100 m long section of the forcemain west of the pump station, will be completed by others during a different stage. At Ogden Point, the forcemain crosses the entrance to Victoria Harbour via a subsea horizontal directional drill (HDD) to the new McLoughlin Point WWTP. The design and construction of HDD crossing and of the WWTP are currently underway, and is being completed by others.

This report describes the physical setting and geological setting of the project, outlines the scope of the geotechnical exploration completed by Stantec and presents the results of the borehole exploration work, in-situ testing, instrumentation, and laboratory testing.

For ease of understanding, Stantec has split the preliminary Clover Point Forcemain alignment into three zones represented by common soil characteristics and engineering properties based on published surficial geology mapping (Monahan and Levson, 2000). The three geotechnical zones are presented on Drawing 1, in Appendix B, and summarized as follows:

Zone 1 – Ogden Point (10+000 to 0+450 m)

Zone 2 – James Bay Seawall (10+450 to 10+900 m)

Zone 3 – Holland Point to near Clover Point (10+900 to 13+200 m)

1.2 PURPOSE AND SCOPE

The purpose of the geotechnical exploration was to obtain information on the subsurface conditions beneath the preliminary Clover Point forcemain alignment to characterize the soil conditions to support the indicative design. In addition, borehole locations were selected to target specific areas along the preliminary alignment where key geotechnical considerations/issues were identified by Stantec during our terrain assessment of the Dallas Road cliffs (Reference "Dallas Road Cliffs, Historic Foreshore Erosion Assessment" prepared by Stantec Consulting Ltd., dated May 30, 2017).

The types of test holes for the geotechnical exploration, as well as the locations and type of testing were selected based the following considerations:

July 27, 2017

- Areas which may be underlain by shallow bedrock;
- Areas potentially underlain by significant amounts of fill placed for road widening or pedestrian walkways; and
- Areas where the stability of existing slopes and could be impacted

The resulting execution strategy of the Clover Point Forcemain geotechnical exploration work consisted of the following:

- Geotechnical drilling using percussive air rotary (ODEX) and solid stem auger techniques,
 with sampling by means of split spoon, and grab sampling;
- In-situ testing by means of standard penetration testing (SPT's) and dynamic cone penetration tests (DCPT's);
- Installation of three (3) slope inclinometers;
- Installation of a nested standpipe piezometer; and,
- Laboratory testing, including moisture content, Atterberg Limits, particle size, fines content, pH, conductivity, and sulphate content testing.

1.3 PROJECT DESCRIPTION

Some portions of the preliminary Clover Point Forcemain alignment will be located within the existing Dallas Road roadway. The majority of the alignment will be located within adjacent grassy park areas, and asphalt paved parking areas and walkways along Dallas Road.

We understand that the Clover Point Forcemain will be 1350 mm diameter and that the pipe invert depth will generally range from 2.5 to 3.8 m below the existing ground surface. At select locations, including the Clover Point tie-in, the pipe will be founded deeper, with a pipe invert depth of up to 5.4 m below the existing ground surface.

The project chainage of the forcemain for this report begins at the west end of the alignment at 10+000 m near the intersection of Dallas Road with St. Lawrence Street, and terminates at approximately 13+220 m near Clover Point at the east end of the alignment. The chainage notation is opposite to the forcemain's flow direction, which runs from east to west. For the purpose of this report, the alignment will be described from west to east, in accordance with the chainage notation.

2.0 SITE DESCRIPTION

2.1 PHYSICAL SETTING

The ground surface along the length of the preliminary alignment ranges from flat to moderately sloping. The west third of the alignment, between St. Lawrence Street (chainage 10+000 m) and Boyd Street (chainage 10+800 m) is gently sloping, increasing in elevation from 4 m near St. Lawrence Street, to 7 m near Boyd Street along an 800 m lineal span.

The middle third of the alignment is moderately sloping, with a general increase in ground surface elevation from 7 m near Boyd Street, to 23 m in front of Beacon Hill Park (chainage 11+960) along a 1160 m lineal span.

The eastern third of the alignment is gently to moderately sloping, with a minor undulation near Linden Avenue but a general decrease in ground surface elevation from 23 m in front of Beacon Hill Park, to 13 m near the proposed Clover Point Pump Station (chainage 13+200 m) along a 1240 m lineal span.

The slope of the ground surface orthogonal to the preliminary forcemain alignment is generally flat to gently sloping, and is at least 15 m from the edge of slopes leading down to the beach, except for three spans: near the James Bay seawall, near Paddon Avenue and near Douglas Street. The James Bay seawall spans approximately 500 m from Dock Street to Lewis Street and has a height of approximately 6 m measured from the ground surface behind the wall to the ground surface in front of the wall. Based on the preliminary alignment, the forcemain would be located approximately 3.7 m behind the edge of the seawall. At Paddon Avenue and Douglas Street, the preliminary alignment would position the forcemain a distance of approximately 5 m from the edge of a slope which leads down to the beach at a slope of approximately 30 to 35 degrees, and 35 to 40 degrees, respectively.

Existing underground utilities run underneath and/or across Dallas Road along much of the preliminary forcemain alignment, but with a higher concentration of utilities between Ogden Point and Beacon Hill Park near Douglas Street. Overhead power and communication lines also run along the south edge of Dallas Road near Ogden Point, between St. Lawrence Street and Montreal Street.

2.2 GEOLOGICAL SETTING

2.2.1 Setting and Bedrock Geology

The preliminary forcemain alignment is located within the Nanaimo Lowland physiographic subdivision, a strip of low-lying country, extending along the northeast, east and southwest coasts of Vancouver Island from Sayward to Jordan River, west of Victoria (Holland 1976).

July 27, 2017

The bedrock underlying the preliminary forcemain alignment is Jurassic-age Westcoast Crystalline Complex comprising quartz diorite, tonalite, horneblende-plagioclase gneiss, quartz-feldspar gneiss, amphibolite, diorite, agmatite, gabbro, marble and metasediments, including the Wark-Colquitz Complex (Clapp 1913, Cui 2015). Bedrock outcrops along the shoreline between Finlayson Point to Holland Park. Fault-zone mylonites in the Jurassic-age gneiss have been identified on the west side of Clover Point (Johnston et al. 2013). The active Leech River Fault Zone is located approximately 5 km west of Ogden Point (Morell et al. 2017) and the Devil's Mountain Fault Zone lies approximately 2.5 km south and offshore of the Clover Point Forcemain (Barrie and Greene 2015).

2.2.2 Quaternary History

During the last major glaciation (25,000-10,000 ybp) glaciers formed in the Vancouver Island Mountains and Coast Mountains and advanced down the Strait of Georgia to southeastern Vancouver Island after 19,000 ybp. During the glacial maximum (~15,000 ybp) southern Vancouver Island was completely covered by an ice sheet that flowed south-southwesterly across Juan de Fuca Strait and deposited Cordilleran till (Alley and Chatwin 1979). As the climate began to ameliorate, deglaciation was by downwasting and southern Vancouver Island was ice-free by 12,500 ybp (Clague 1981). During this period, the coastline was depressed due to glacio-isostatic effects such that marine waters invaded lowland areas below 75 meters elevation and glaciomarine sediments were deposited (Mathews et al. 1970). However, present sea level was attained as early as 11,700 ybp at Victoria (Clague 1981).

2.2.3 Surficial Geology

Regional (1:25,000) scale surficial geology mapping of the Victoria area provides an overview of surficial materials underlying the preliminary forcemain alignment (Monahan and Levson 2000). The alignment is underlain by areas of thin soil, with bedrock near or at the surface, interspersed with deposits of Victoria Clay. Victoria Clay is a glaciomarine sediment deposited when the coastline was depressed, at the end of the last glaciation. Four distinct units were mapped underlying the preliminary forcemain alignment. These units are summarized in **Table 1**; unit descriptions are from Geoscience Map 2000-2 (Monahan and Levson 2000).

Table 1 Surficial Geology Units along the Preliminary Forcemain Alignment

UNIT R2 UNIT C2	VICTORIA CLAY - INTERMEDIATE BETWEEN UNITS R2 AND C2, INCLUDING UNDIFFERENTIATED AREAS This unit mainly includes areas where soil profiles typical of units R2 and C2 occur together on a scale that is not mappable with the data available. This unit also includes areas where there is greater than 5 metres of Victoria clay, but where the thickness of the lower grey clay facies is less than 3 metres. AREAS WITH BEDROCK AT OR NEAR THE SURFACE - THIN SOIL COVER WITH SCATTERED BEDROCK OUTCROP Generally consists of shallow soils over bedrock. In much of Greater Victoria, this unit includes areas with less than 5 metres of Victoria Clay, mainly the brown clay facies, overlying thin older Pleistocene deposits or bedrock. Scattered outcrops occur throughout the unit, and bedrock is commonly found in the upper five metres (e.g. in utility line excavations). The thickness of older Pleistocene deposits in most places is less than a few metres, but may locally be up to 10 metres. - UNIT R2a consists of those areas of unit R2 where thicknesses of older Pleistocene deposits between 5 and 10 metres can be	Sta. 10+000 to Sta. 10+150 Sta. 10+150 to Sta. 10+500 Sta. 10+800 to Sta. 11+350 Sta. 11+450 to Sta. 11+800

3.0 GEOTECHNICAL SUBSURFACE EXPLORATION

3.1 SUMMARY

Stantec carried out a geotechnical subsurface exploration for the Clover Point Forcemain between June 19 and July 4, 2017 in order to support indicative design for the routing and installation of the forcemain.

The scope of the geotechnical exploration work consisted of the following:

- Seven (7) percussive air rotary (ODEX) boreholes;
- Seventeen (17) solid-stem auger boreholes;
- Three (3) slope inclinometer casing installations;
- One (1) nested standpipe piezometer installation

Test hole coordinates were recorded with a handheld Global Positioning System (GPS) device with an accuracy of approximately +/-3 m, with additional measurements taken in the field referenced to fixed landmarks (roadway intersections, curb returns, etc.). Upon plotting the GPS coordinates onto the drawings, if substantial error was noted when compared with the additional measurements to the fixed landmarks, the test hole location was adjusted on the drawing in accordance with the additional field measurements. Test hole elevations were approximated using LiDAR elevation contours provided by the CRD, as well as a topographic survey of the preliminary forcemain alignment sub-contracted by Stantec to McElhanney Surveys. Contour lines are shown on plan drawings included in Appendix B.

Soil samples were collected from boreholes by means of grab sampling and/or split spoon sampling. Standard Penetration Tests (SPTs) or Dynamic Cone Penetration Tests were completed in the ODEX and solid-stem auger boreholes.

The auger and ODEX drilling was performed using a Mobile B54, truck-mounted drill rig. The drill rig and associated support vehicles, equipment and tooling (including the 200 psi, 300 ft³/min ODEX air compressor) are owned and operated by Geotech Drilling Services Ltd. (Geotech Drilling), located in Delta, BC.

Full-time review of the subsurface exploration work was carried out by a Stantec geotechnical field engineer, who classified the soils encountered, recorded borehole coordinates and SPT/DCPT blow counts, and collected representative soil samples. The soil samples were returned to the Stantec geotechnical laboratory in Burnaby, BC for classification and index testing.

3.2 GEOTECHNICAL DRILLING EXPLORATION

Descriptions of the percussive air rotary (ODEX) and solid stem auger drilling methodologies used for the boreholes are provided in the following sub-sections.

Detailed borehole logs describing the soil and groundwater conditions encountered, and results of the laboratory classification and index testing are included in Appendix C.

Soil descriptions presented on the borehole logs are based on the grab samples and split spoon samples collected at discrete intervals and are in general accordance with ASTM D2487 and D2488 for the Unified Soil Classification System (USCS) and the information presented on the "Symbols and Terms Used in Borehole and Test Pit Records" in Appendix C. Where the quantity of a soil type is sufficiently small, less than 5% and 15% for fine grained (passing the No. 200 sieve) and coarse grained (retained on the No. 200 sieve) soils, respectively, it is not reported on the borehole logs, in accordance with the USCS classification method.

3.2.1 Percussive Air Rotary (ODEX) Drilling

Seven (7) percussive, downhole hammer air rotary (ODEX) boreholes were completed using 125 mm diameter steel casing. **Table 2** presents a summary of the ODEX boreholes, and includes borehole coordinates, elevations, depths, and methods for sampling and in-situ testing.

In the ODEX drilling method, an eccentric, convex drill bit covered with carbide buttons penetrates overburden and rock formations via a reciprocating, jackhammer-like action. The downhole hammer is pneumatically driven via a constant stream of air, which also lifts drill cuttings away from the drill bit and up the casing to the surface.

In general, the ODEX drilling method was used to drill select deep boreholes near Paddon Avenue and Douglas Street for slope stability analyses and for permanent casing installations (i.e., slope inclinometers and standpipe piezometer). The ability to penetrate through very dense granular material (including cobbles and boulders) to target depth (into glacial till or into the underlying bedrock) allowed successful completion of boreholes BH17-12a to BH17-14, BH17-16 and BH17-24.

Sampling of both coarse-grained soils (i.e., sands and gravels) and fine-grained soils (i.e., silts and clays) in the ODEX boreholes was completed with split spoons and occasionally via grab sampling from drill cuttings collected from the air return. Samples were placed in plastic bags and transported to the Stantec laboratory in Burnaby, BC for further classification and index testing. SPT blow counts were recorded during split-spoon sampling. Further details regarding the SPTs are provided in Section 3.3.1.

July 27, 2017

NOTES:

(1) For project chainage, refer to Drawings 2-1 to 2-9 in Appendix B

Boreholes BH17-03 and BH17-04 were originally planned as auger boreholes, but upon attempting to drill at these locations, it was discovered that a layer of concrete underlay the surficial asphalt and impeded the auger from advancing. Accordingly, the ODEX method was used to drill through the concrete and complete these two shallow boreholes.

Borehole BH17-24 was not originally planned, but was added to supplement the subsurface information near the intersection of Dallas Rd with Douglas Street via additional sampling and SPT testing, and the installation of a standpipe piezometer.

Boreholes BH17-12a, BH17-13, BH17-14, BH17-16 and BH17-24 were advanced through overburden soils and into bedrock as planned.

Due to the installation of slope inclinometer casings in boreholes BH17-12a, BH17-14 and BH17-16, a combination of cement-bentonite grout and silica sand was used to backfill these holes, which were each capped with a steel casing cover concreted to match the surrounding grade. Similarly, the standpipe piezometer at BH17-24 was backfilled using a combination of bentonite chips and silica sand, and also capped with a steel casing cover concreted to match the surrounding grade. Boreholes BH17-03, BH17-04 and BH17-13 were backfilled using a

July 27, 2017

combination of drill cuttings and silica sand. Bentonite seals were placed in compliance with the BC Groundwater Protection Regulation at the bottom of each borehole, at 6 m intervals, and below the surficial concrete plug.

3.2.2 Auger Drilling

Seventeen (17) auger boreholes were advanced using 140 mm diameter solid-stem, continuous flight auger drill rods. **Table 3** presents a summary of the auger boreholes, and includes borehole coordinates, elevations, depths, and methods for sampling and in-situ testing.

The solid stem drilling method was used to drill the majority of the boreholes along the preliminary Clover Point Forcemain alignment. In general, auger boreholes were advanced to a depth of 4.6 m (15 ft.) or practical refusal, to evaluate the soil conditions in the vicinity of the forcemain invert. At the James Bay seawall, the auger boreholes were advanced to depths of up to 7.6 m (25 ft.) in order to determine the composition of the native soil at the approximate subgrade level immediately below the inferred foundation depth of the concrete retaining wall.

Sampling of soils from the auger boreholes was completed mostly by collection of grab samples, with occasional split spoon sampling. Grab samples and split spoon samples were placed in plastic bags and transported to the Stantec laboratory for further classification and index testing. SPT and DCPT blow counts were recorded on borehole logs and used to characterize the compactness or consistency of the soils. Further details regarding the SPTs and DCPTs are provided in Sections 3.3.1 and 3.3.2.

July 27, 2017

NOTES:	•				•	•	

(1) For project chainage, refer to Drawings 2-1 to 2-9 in Appendix B

All auger boreholes were completed to their targeted depth with the exception of boreholes BH17-07, BH17-10, BH17-11, BH17-15 and BH17-19. Boreholes BH17-07, BH17-10, BH17-15 and BH17-19 were terminated prior to reaching the target depth due to auger refusal on dense granular soils, hard clay soils, cobbles or bedrock. Drilling of borehole BH17-11 was abandoned due to mechanical breakdown of the auger drill head following a successful DCPT test to target depth at this location.

Borehole BH17-23 was not originally planned, but was added in order to further evaluate the fill thickness near the intersection of Dallas Road with Paddon Avenue. Borehole BH17-12b was also

July 27, 2017

not originally planned, but was added to obtain DCPT blow counts in the native soils adjacent to borehole BH17-12a.

The auger boreholes were backfilled with drill cuttings, and bentonite seals were placed in compliance with the BC *Groundwater Protection Regulation*. Boreholes completed within the existing roadways, sidewalks or parking stalls were reinstated with a concrete patch.

3.3 IN-SITU TESTING

3.3.1 Standard Penetration Testing

SPTs were performed using 50.8 mm outside diameter, un-lined split spoon samplers driven with automatic safety hammers and in general accordance with ASTM D1586. Specifically, the SPTs involved driving the split spoon sampler connected by AWJ-rods with 63.5 kg hammers, falling from a height of 760 mm. Blow counts were recorded over four 150 mm intervals during the testing. The SPT blow counts are the cumulative blows for the second and third 150 mm penetration (total 300 mm or less than 300 mm in cases of refusal for further penetration) are reported on the borehole logs in Appendix C. Split spoon samples were placed in plastic bags and transported to the Stantec laboratory for further visual classification and index testing.

SPTs were generally performed on ODEX boreholes except for the tests in two auger boreholes. The steel drill casing of the ODEX boreholes remained in the ground during the SPT testing. The two auger boreholes in which SPT testing were carried out (BH17-01 and BH17-17) remained clean and open during the test.

3.3.2 Dynamic Cone Penetration Testing

DCPTs were performed using the same automatic safety hammer for SPTs to drive a conical tip at the end of the AWJ-rod string in lieu of an open soil sampler. Unlike SPTs, a soil sample is not retrieved. Instead, the DCPT is driven until either target depth or practical refusal is encountered, thereby generating an approximate, near-continuous profile of the soil compactness/consistency. The cone has a 30 mm diameter blunt tip and tappers at 45 degrees to 60 mm diameter, followed by a sleeve length of 150 mm.

Blow counts for the DCPT were recorded in 150 mm intervals and reported in the borehole logs in terms of total blows per 300 mm penetration.

DCPTs were generally performed starting from the upper 1.5 m in the auger borehole locations prior to drilling.

3.4 INSTRUMENTATION

3.4.1 Slope Inclinometers

A total of three (3) slope inclinometers were installed at select locations along the preliminary forcemain alignment. The slope inclinometer locations were selected in areas which were considered to be in close proximity of the adjacent slopes. One (1) slope inclinometer was installed near Paddon Avenue in borehole BH17-12a, and two (2) slope inclinometers were installed near Douglas Street in boreholes BH17-14 and BH17-16. The purpose of the slope inclinometers is to establish infrastructure that will allow for the monitoring of potentially deep seated slope movements of the cliffs during and after the construction of the forcemain.

The slope inclinometer installation consisted of boring through surficial fills and overburden soils, and advancing into the underlying bedrock. The 70 mm (2.75 inch) outer diameter ABS plastic snap seal inclinometer casing was then installed within the steel drill casing. As the steel drill casing was extracted, the annulus between the slope inclinometer casing and the borehole sidewalls was backfilled with a cement-bentonite grout.

The casings for the slope inclinometers were extended into the bedrock, as presented in **Table 4**, in order to allow for reference points for lateral movements above the bedrock surface.

Table 4 Summary of Slope Inclinometers

NOTES:

(1) For project chainage, refer to Drawings 2-1 to 2-9 in Appendix B

The slope inclinometer casings are monitored using a Digital Inclinometer monitoring system, model IC3205, supplied by RST Instruments Ltd., Maple Ridge, BC. The RST Digital Inclinometer monitoring system consists of an inclinometer probe, a graduated cable system, and a portable readout and data storage device. For monitoring, the probe is first inserted to the bottom of the inclinometer casings, then slowly drawn upwards, with measurements taken at 0.5 m intervals. The first survey establishes the baseline readings for the casing, with subsequent monitoring intervals compared to the baseline monitoring event to reveal changes in the lateral profile if movement occurs. Readings are recorded and stored in a handheld PC and subsequently downloaded into computer software for processing. Subsequent monitoring of the inclinometers

July 27, 2017

shows movement in the A-Axis (parallel to the slope face) and the B-Axis (perpendicular to the slope face).

The data from the field is collected containing the field readings for A0 (A+, or downslope), A180 (A-, or upslope), B0 (B+) and B180 (B-) by depth. The data is imported into a database and the displacement at each discrete reading depth is calculated by taking the difference between the latest reading and the base-line reading. The displacement is then summed along the length of the pipe to create a cumulative displacement graph for both the "A" and "B" axes. If lateral movement was observed below the known bedrock level, a bias correction is applied to the data.

Baseline slope inclinometer readings were collected from the three slope inclinometer casings in the days following their installation. Additional readings are required to determine the degree of movement at each borehole location. As previously noted, borehole coordinates- including those for the three slope inclinometers- were recorded in the field using a handheld GPS. We are currently awaiting surveyed coordinates of the slope inclinometer casing covers, which will be collected by a BC Land Surveyor. Additional survey readings should be collected in conjunction with each subsequent slope inclinometer reading during construction and should be the responsibility of the contractor.

3.5 STANDPIPE PIEZOMETER

At borehole BH17-24, a standpipe piezometer consisting of two nested 25 mm diameter PVC pipe casings were installed to enable groundwater level readings.

Installation details for the standpipe piezometer are presented in **Table 5** below.

Table 5 Summary of Standpipe Piezometer Installation

Water level readings were recorded on June 29, July 4 and July 18, 2017, or three, eight and 22 days, respectively, after the completion of the well installation. The readings indicate an equilibrium water level of 13.9 m below the existing ground surface.

4.0 LABORATORY TESTING

4.1 SUMMARY

Laboratory testing was conducted on split spoon samples and grab samples obtained during the geotechnical subsurface exploration work. A summary of the laboratory testing is presented in **Table 6**.

Natural moisture content, Atterberg limits, particle size analyses tests and fines content measurements were performed at the Stantec laboratory in Burnaby, BC. Testing of pH, conductivity and sulphate content were carried at the Maxxam Analytics laboratory in Burnaby, BC.

Table 6 Summary of Laboratory Testing

Laboratory Test	Number of Test Completed
Natural Moisture Content	130
Atterberg Limits	13
Particle Size Distribution	11
Fines Content Measurement (Particles less than 0.075 mm in size, passing sieve No. 200)	38
pH Testing	6
Electrical Conductivity Testing	6
Soluble Sulphate Testing	6

4.2 LABORATORY TESTING PROCEDURES

4.2.1 Natural Moisture Content

The Natural Moisture Content (w) of soil is defined as the ratio of the mass of water contained in the pore spaces of the soil to the mass of solids in the soil, expressed as a percentage.

Measurement of moisture content was performed in general accordance with ASTM D2216.

Natural moisture content measurements are presented on the borehole logs in Appendix C.

4.2.2 Atterberg Limits

Atterberg limits describe the consistency and plasticity of fine-grained soils with varying degrees of moisture. Atterberg limits tests are used to determine the moisture contents at which soil behavior becomes liquid or brittle. The Liquid Limit (LL) represents the moisture content at which the soil begins to flow like a liquid, and the Plastic Limit (PL) represents the moisture content at

July 27, 2017

which it ceases to be plastic and becomes brittle. Subtracting the plastic limit from the liquid limit yields the Plasticity Index (PI). The PI defines the typical range of moisture contents for a soil.

The Atterberg limits were measured using the multi-point method (Method A), described in ASTM D4318. The PI is defined as follows:

$$PI = LL - PL$$

The Liquidity Index (LI) is defined as follows:

$$LI = (w - PL)/PI$$

Where "w" is the natural moisture content of the soil sample.

Atterberg limits test results are presented in Appendix D.1 and on the borehole logs in Appendix C.

4.2.3 Particle Size Distribution and Fines Content

Tests for particle size distribution were performed in general accordance with ASTM D421 and ASTM D422. In some cases, only the amount of material in the soil samples finer than 0.075 mm nominal diameter was measured. In these cases, testing was completed in general accordance with ASTM D1140 (Method A). Particle size distribution test results are presented in Appendix D.2, and summary of particle size and fines content test results are presented on the borehole logs in Appendix C.

4.2.4 pH, Conductivity and Sulphate Content

Testing of pH, conductivity and sulphate content for selected soil samples was completed at the Maxxam Analytics laboratory in Burnaby, BC, in general accordance with SM 22 4500-H+B, SM 22 2510 B, and SM 22 4500-SO42- Em respectively. The results are presented in Appendix D.3.

5.0 CLOSURE

This report was prepared for the exclusive use of the CRD and its agents for specific application to the Clover Point Forcemain Indicative Design Project. Any use of this report or the material contained herein by third parties, or for other than the intended purpose, should first be approved in writing by Stantec.

Use of this report is subject to the Statement of General Conditions included in Appendix A. It is the responsibility of the Capital Regional District, who is identified as "the Client" within the Statement of General Conditions, and their agents to review the conditions and notify Stantec should any of them not be satisfied.

We trust that this report meets your present requirements. If you have any questions or require additional information, please do not hesitate to contact the undersigned.

Respectfully submitted,

STANTEC CONSULTING LTD.

Appendix A Statement of General Conditions July 27, 2017

Appendix A STATEMENT OF GENERAL CONDITIONS

USE OF THIS REPORT: This report has been prepared for the sole benefit of the Client or its agent and may not be used by any third party without the express written consent of Stantec and the Client. Any use which a third party makes of this report is the responsibility of such third party.

BASIS OF THE REPORT: The information, opinions, and/or recommendations made in this report are in accordance with Stantec's present understanding of the site specific project as described by the Client. The applicability of these is restricted to the site conditions encountered at the time of the investigation or study. If the proposed site specific project differs or is modified from what is described in this report or if the site conditions are altered, this report is no longer valid unless Stantec is requested by the Client to review and revise the report to reflect the differing or modified project specifics and/or the altered site conditions.

STANDARD OF CARE: Preparation of this report, and all associated work, was carried out in accordance with the normally accepted standard of care in the state or province of execution for the specific professional service provided to the Client. No other warranty is made.

INTERPRETATION OF SITE CONDITIONS: Soil, rock, or other material descriptions, and statements regarding their condition, made in this report are based on site conditions encountered by Stantec at the time of the work and at the specific testing and/or sampling locations. Classifications and statements of condition have been made in accordance with normally accepted practices which are judgmental in nature; no specific description should be considered exact, but rather reflective of the anticipated material behavior. Extrapolation of in situ conditions can only be made to some limited extent beyond the sampling or test points. The extent depends on variability of the soil, rock and groundwater conditions as influenced by geological processes, construction activity, and site use.

VARYING OR UNEXPECTED CONDITIONS: Should any site or subsurface conditions be encountered that are different from those described in this report or encountered at the test locations, Stantec must be notified immediately to assess if the varying or unexpected conditions are substantial and if reassessments of the report conclusions or recommendations are required. Stantec will not be responsible to any party for damages incurred as a result of failing to notify Stantec that differing site or sub-surface conditions are present upon becoming aware of such conditions.

PLANNING, DESIGN, OR CONSTRUCTION: Development or design plans and specifications should be reviewed by Stantec, sufficiently ahead of initiating the next project stage (property acquisition, tender, construction, etc), to confirm that this report completely addresses the elaborated project specifics and that the contents of this report have been properly interpreted. Specialty quality assurance services (field observations and testing) during construction are a necessary part of the evaluation of sub-subsurface conditions and site preparation works. Site work relating to the recommendations included in this report should only be carried out in the presence of a qualified geotechnical engineer; Stantec cannot be responsible for site work carried out without being present.

Appendix C Borehole Logs July 27, 2017

Appendix C BOREHOLE LOGS

SYMBOLS AND TERMS USED ON BOREHOLE AND TEST PIT RECORDS

SOIL DESCRIPTION

Terminology describing common soil genesis:

Rootmat	- vegetation, roots and moss with organic matter and topsoil typically forming a mattress at the ground surface
Topsoil	- mixture of soil and humus capable of supporting vegetative growth
Peat	- mixture of visible and invisible fragments of decayed organic matter
Till	- unstratified glacial deposit which may range from clay to boulders
Fill	- material below the surface identified as placed by humans (excluding buried services)

Terminology describing soil structure:

Desiccated	- having visible signs of weathering by oxidization of clay minerals, shrinkage cracks, etc.	
Fissured	d - having cracks, and hence a blocky structure	
Varved	- composed of regular alternating layers of silt and clay	
Stratified	- composed of alternating successions of different soil types, e.g. silt and sand	
Layer	- > 75 mm in thickness	
Seam	- 2 mm to 75 mm in thickness	
Parting	- < 2 mm in thickness	

Terminology describing soil types:

The classification of soil types are made on the basis of grain size and plasticity in accordance with the Unified Soil Classification System (USCS) (ASTM D 2487 or D 2488) which excludes particles larger than 75 mm. For particles larger than 75 mm, and for defining percent clay fraction in hydrometer results, definitions proposed by Canadian Foundation Engineering Manual, 4th Edition are used. The USCS provides a group symbol (e.g. SM) and group name (e.g. silty sand) for identification.

Terminology describing cobbles, boulders, and non-matrix materials (organic matter or debris):

Terminology describing materials outside the USCS, (e.g. particles larger than 75 mm, visible organic matter, and construction debris) is based upon the proportion of these materials present:

Trace, or occasional	Less than 10%
Some	10-20%
Frequent	> 20%

Terminology describing compactness of cohesionless soils:

The standard terminology to describe cohesionless soils includes compactness (formerly "relative density"), as determined by the Standard Penetration Test (SPT) N-Value - also known as N-Index. The SPT N-Value is described further on page 3. A relationship between compactness condition and N-Value is shown in the following table.

Compactness Condition	SPT N-Value
Very Loose	<4
Loose	4-10
Compact	10-30
Dense	30-50
Very Dense	>50

Terminology describing consistency of cohesive soils:

The standard terminology to describe cohesive soils includes the consistency, which is based on undrained shear strength as measured by *in situ* vane tests, penetrometer tests, or unconfined compression tests. Consistency may be crudely estimated from SPT N-Value based on the correlation shown in the following table (Terzaghi and Peck, 1967). The correlation to SPT N-Value is used with caution as it is only very approximate.

Completeness	Undrained Sh	Approximate	
Consistency	kips/sq.ft.	kPa	SPT N-Value
Very Soft	<0.25	<12.5	<2
Soft	0.25 - 0.5	12.5 - 25	2-4
Firm	0.5 - 1.0	25 - 50	4-8
Stiff	1.0 - 2.0	50 – 100	8-15
Very Stiff	2.0 - 4.0	100 - 200	15-30
Hard	>4.0	>200	>30

ROCK DESCRIPTION

Except where specified below, terminology for describing rock is as defined by the International Society for Rock Mechanics (ISRM) 2007 publication "The Complete ISRM Suggested Methods for Rock Characterization, Testing and Monitoring: 1974-2006"

Terminology describing rock quality:

reministry accombing rock quality:		
RQD	Rock Mass Quality	
0-25	Very Poor Quality	
25-50	Poor Quality	
50-75	Fair Quality	
75-90	Good Quality	
90-100	Excellent Quality	

Alternate (Colloquial) Rock Mass Quality		
Very Severely Fractured	Crushed	
Severely Fractured	Shattered or Very Blocky	
Fractured	Blocky	
Moderately Jointed	Sound	
Intact	Very Sound	

RQD (Rock Quality Designation) denotes the percentage of intact and sound rock retrieved from a borehole of any orientation. All pieces of intact and sound rock core equal to or greater than 100 mm (4 in.) long are summed and divided by the total length of the core run. RQD is determined in accordance with ASTM D6032.

SCR (Solid Core Recovery) denotes the percentage of solid core (cylindrical) retrieved from a borehole of any orientation. All pieces of solid (cylindrical) core are summed and divided by the total length of the core run (It excludes all portions of core pieces that are not fully cylindrical as well as crushed or rubble zones).

Fracture Index (FI) is defined as the number of naturally occurring fractures within a given length of core. The Fracture Index is reported as a simple count of natural occurring fractures.

Terminology describing rock with respect to discontinuity and bedding spacing:

Spacing (mm)	Discontinuities	Bedding
>6000	Extremely Wide	-
2000-6000	Very Wide	Very Thick
600-2000	Wide	Thick
200-600	Moderate	Medium
60-200	Close	Thin
20-60	Very Close	Very Thin
<20	Extremely Close	Laminated
<6	-	Thinly Laminated

Terminology describing rock strength:

Strength Classification	Grade	Unconfined Compressive Strength (MPa)
Extremely Weak	RO	<1
Very Weak	R1	1 – 5
Weak	R2	5 – 25
Medium Strong	R3	25 – 50
Strong	R4	50 – 100
Very Strong	R5	100 – 250
Extremely Strong	R6	>250

Terminology describing rock weathering:

Term	Symbol	Description
Fresh	W1	No visible signs of rock weathering. Slight discoloration along major discontinuities
Slightly	W2	Discoloration indicates weathering of rock on discontinuity surfaces. All the rock material may be discolored.
Moderately	W3	Less than half the rock is decomposed and/or disintegrated into soil.
Highly	W4	More than half the rock is decomposed and/or disintegrated into soil.
Completely	W5	All the rock material is decomposed and/or disintegrated into soil. The original mass structure is still largely intact.
Residual Soil	W6	All the rock converted to soil. Structure and fabric destroyed.

STRATA PLOT

Strata plots symbolize the soil or bedrock description. They are combinations of the following basic symbols. The dimensions within the strata symbols are not indicative of the particle size, layer thickness, etc.

SAMPLE TYPE

SS	Split spoon sample (obtained by performing the Standard Penetration Test)
ST Shelby tube or thin wall tube	
DP	Direct-Push sample (small diameter tube sampler hydraulically advanced)
PT	Piston tube sample
GS	Grab sample
HQ, NQ, BQ, etc.	Rock core samples obtained with the use of standard size diamond coring bits.

WATER LEVEL MEASUREMENT

RECOVERY

For soil samples, the recovery is recorded as the length of the soil sample recovered. For rock core, recovery is defined as the total cumulative length of all core recovered in the core barrel divided by the length drilled and is recorded as a percentage on a per run basis.

N-VALUE

Numbers in this column are the field results of the Standard Penetration Test: the number of blows of a 140 pound (63.5 kg) hammer falling 30 inches (760 mm), required to drive a 2 inch (50.8 mm) O.D. split spoon sampler one foot (300 mm) into the soil. In accordance with ASTM D1586, the N-Value equals the sum of the number of blows (N) required to drive the sampler over the interval of 6 to 18 in. (150 to 450 mm). However, when a 24 in. (610 mm) sampler is used, the number of blows (N) required to drive the sampler over the interval of 12 to 24 in. (300 to 610 mm) may be reported if this value is lower. For split spoon samples where insufficient penetration was achieved and N-Values cannot be presented, the number of blows are reported over sampler penetration in millimetres (e.g. 50/75). Some design methods make use of N-values corrected for various factors such as overburden pressure, energy ratio, borehole diameter, etc. No corrections have been applied to the N-values presented on the log.

DYNAMIC CONE PENETRATION TEST (DCPT)

Dynamic cone penetration tests are performed using a standard 60 degree apex cone connected to 'A' size drill rods with the same standard fall height and weight as the Standard Penetration Test. The DCPT value is the number of blows of the hammer required to drive the cone one foot (300 mm) into the soil. The DCPT is used as a probe to assess soil variability.

OTHER TESTS

S	Sieve analysis
Н	Hydrometer analysis
k	Laboratory permeability
Υ	Unit weight
Gs	Specific gravity of soil particles
CD	Consolidated drained triaxial
CU	Consolidated undrained triaxial with pore
CU	pressure measurements
UU	Unconsolidated undrained triaxial
DS	Direct Shear
С	Consolidation
Qυ	Unconfined compression
Iр	Point Load Index (I_p on Borehole Record equals I_p (50) in which the index is corrected to a reference diameter of 50 mm)

Ţ	Single packer permeability test; test interval from depth shown to bottom of borehole
	Double packer permeability test; test interval as indicated
Ŷ	Falling head permeability test using casing
Ĭ	Falling head permeability test using well point or piezometer

Remarks:

Maxxam Analytics' laboratories are accredited to ISO/IEC 17025:2005 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Maxxam are based upon recognized Provincial, Federal or US method compendia such as CCME, MDDELCC, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Maxxam's profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Maxxam in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported: unless indicated otherwise, associated sample data are not blank corrected.

Maxxam Analytics' liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Maxxam has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Maxxam, unless otherwise agreed in writing.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.

Results relate to samples tested.

This Certificate shall not be reproduced except in full, without the written approval of the laboratory.

Reference Method suffix "m" indicates test methods incorporate validated modifications from specific reference methods to improve performance.

* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.

N/A = Not Applicable

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

QC Standard: A sample of known concentration prepared by an external agency under stringent conditions. Used as an independent check of method accuracy.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (absolute difference <= 2x RDL).
